ABSTRACT

The CALO Meeting Assistant provides for distributed meeting capture, annotation, automatic transcription and semantic analysis of multiparty meetings, and is part of the larger CALO personal assistant system. This paper summarizes the CALO-MA architecture and its speech recognition and understanding components, which include real-time and offline speech transcription, dialog act segmentation and tagging, question-answer pair identification, action item recognition, decision extraction, and summarization.

Index Terms— multiparty meetings processing, speech recognition, spoken language understanding

1. INTRODUCTION

In most organizations, staff spend many hours each week in meetings, and technological advances have made it possible to routinely record and store meeting data. Consequently, automatic means of transcribing and understanding meetings would greatly increase productivity of both meeting participants and non-participants. The meeting domain has a large number of subdomains including judicial and legislative proceedings, lectures, seminars, board meetings, and a variety of less formal group meeting types. All these meeting types could benefit immensely from the development of automatic speech recognition (ASR), understanding, and information extraction technologies that could be linked with a variety of online information systems.

In this paper we present the meeting recognition and understanding system for the CALO Meeting Assistant (CALO-MA) project. CALO-MA is an automatic agent that assists meeting participants, and is part of the larger CALO [1] effort to build a “Cognitive Assistant that Learns and Organizes” funded by the Defense Advanced Research Projects Agency (DARPA). CALO-MA supports multiparty meetings with a variety of information capture and annotation tools. Meetings are recorded via client software running on participants’ laptop computers. The system is aware of each participant’s identity. Meetings may be geographically distributed as long as a broadband Internet connection to the server is available (a phone-based interface is being developed as well). The client software captures the participants’ audio signals, as well as optional handwriting recorded by digital pens. During the meeting, a real-time transcript is available to the participants to which annotations may be attached. Real-time chat via keyboard input is also supported. All interactions are logged in a database, and at the conclusion of the meeting various further automatic annotation and interpretation technologies are initiated, for later browsing via a web-based interface.

Apart from being highly usable in its present form, the system presents a data collection and research experimentation platform to support ongoing research in natural language and user interface technologies. The nature of multiparty interaction and the extreme variability found in meeting genres makes this domain one of the most difficult challenges for speech and natural language processing today. In the following sections we discuss the speech-based component technologies contributing to CALO-MA, including meeting recognition, dialog act segmentation and tagging, topic segmentation and identification, action item and decision detection, and summarization. We conclude by pointing out research challenges and directions for future work.

2. CALO-MA ARCHITECTURE

2.1. Meeting capture

An early goal of the CALO-MA project was to allow lightweight data capture. Because of this, highly instrumented rooms were avoided in favor of running on each individual’s Java Runtime enabled computer. Meeting participants can attend meetings by using a desktop or laptop running Windows® XP/Vista, Linux, or Mac OS X Leopard. Servers for data transport, data processing, and meeting data browsing run on Windows and Linux environments. If scaling is an issue, additional servers can be integrated into the framework to load balance the various tasks. New efforts will allow participants to conference into a meeting via a bridge between the data transport server and the public switched telephone network (PSTN).

During a meeting, client software sends Voice over Internet Protocol (VoIP) compressed audio data to the server either when energy thresholds are met or when a hold-to-talk mechanism is enabled. The data transport server splits the audio: sending one stream to data processing agents and the other stream to remote meeting participants. Other shared data (text chat, file sharing, digital ink, and collaborative text editing) is handled in a similar manner with data going from client to server and then distributed to both processing agents and other meeting participants. Finally, any processing agents that operate in real-time send their data back to the data transport server which relays the data back to the meeting participants.

2.2. Integration with other CALO components

Both during the live meeting and at any time after the meeting, the meeting data transport server makes available all meeting data to interested parties using XML-RPC interfaces. This allows both local and distributed users and processing agents to access the data in a language-neutral way. Meeting processing agents that are order de-
real-time recognizer obtains 39.7%. We have also demonstrated the
adaptation steps, and a sub-real-time trigram decoder. On a test set
an online speech detector, causal feature normalization and acoustic
language model rescoring, in about 4.2 times real-time (on a 4-core 2.6
GHz Opteron server). The real-time recognition systems consists of
output of standard speech recognizers with this information. Previ-
ous approaches for this task.

In order to exploit the sentence boundary tagged meeting cor-
pora as obtained from other projects such as ICSI and AMI, we also proposed model adaptation [5] and semi-supervised learning [6]
techniques for this task.

5. DIALOG ACT TAGGING

A dialog act is a primitive abstraction or an approximate represen-
tation of the illocutionary force of an utterance, such as question or
backchannel. Dialog acts are designed to be task independent. The
main goal of dialog acts is to provide a basis for further discourse
analysis and understanding. For example, dialog acts can be used to
extract the action items or question/answer pairs in a meeting as dis-
cussed later. Note that dialog acts can be organized in a hierarchical
fashion. For instance, statements can be further categorized as fact
or opinion.

In this project, we followed the MRDA standard [7], which es-
pecially focuses on multiparty meetings. For example, it includes a
set of labels for floor management mechanisms, such as floor grab-
ing and holding, which are common in meetings. In total it has 11
general (such as question) and 39 specific (such as yes/no question)
dialog act tags.

For the CALO project, dialog act tagging is framed as an ut-
terance classification problem using Boosting. More specifically,
we built three different taggers: i) for capturing high-level dia-
log act tags (statement, question, disruption, floor mechanism, and
backchannel) - To build this model, we used only lexical features;
ii) for detecting action motivators since they are shown to help ac-
tion item extraction [8] - For this, we considered only suggestion,
command, and commitment dialog act tags using only lexical fea-
tures; iii) for detecting agreement and disagreement dialog act tags
for single-word utterances, such as yeah or okay - For this task we used prosodic and contextual information.

6. ATTENTION, ADDRESSING, AND REFERENCE

An important intermediate step in the analysis of meeting conversa-
tions is to determine the entities and individuals to which the partic-
ipants are speaking, listening, and referring. This processing step is
essential to downstream summarization in that it provides necessary
situational and discourse context for doing interpretation. To sum-
marize decisions, for example, detecting requests, promises, and dis-
agreements alone is inadequate – the system must understand who
performs these actions, with whom, and in reference to whom.

In contrast to two-party dialogs, multiparty meetings present
new challenges to this problem. Consider the following sentence:“and um if you can get that binding point also maybe with an exam-
ple that would be helpful for John and me”. The challenge here is to
use gaze and dialog context to identify the person marked by “you”
and to resolve any linguistic or gestural references to individuals or
present objects such as “John”.

The addressee identification task is typically approached as an
utterance-level classification where some subset of the participants
in the meeting are identified as addressees. [9] used a combination of
lexical features of the utterance and gaze features from each par-
ticipant to detect addressees in 4-person meetings using Bayesian
networks. For their system, using cues from multiple modalities
proved most effective. But to overcome situations where video is
unavailable or gaze tracking is difficult, the CALO system lever-
ages deeper structural, durational, and lexical features taken from

3. MEETING TRANSCRIPTION

The audio stream from each meeting participant is transcribed into
text by using two separate recognition systems. A real-time rec-
ognizer generates “live” transcripts with 5 to 15 seconds of latency
for immediate display (and possible interactive annotation) in the
CALO user interface. Once the meeting is concluded, a second, of-
line recognition system generates a more accurate transcript for later
processing and serves as the input to the higher-level processing step
described in the following sections.

The offline recognition system is a modified version of the
SRI-ICSI NIST meeting recognizer [2]. It performs a total of
seven recognition passes, including acoustic adaptation and lan-
guage model rescoring, in about 4.2 times real-time (on a 4-core 2.6
GHz Opteron server). The real-time recognition systems consists of
an online speech detector, causal feature normalization and acoustic
adaptation steps, and a sub-real-time trigram decoder. On a test set
where the offline recognizer achieves a word error rate of 26.0%, the
real-time recognizer obtains 39.7%. We have also demonstrated the
use of unsupervised adaptation methods for better recognition [3].

4. DIALOG ACT SEGMENTATION

Output from a standard speech recognition system typically consists of
an unstructured stream of words lacking punctuation, capitaliza-
tion, or formatting. Sentence segmentation for speech enriches the
output of standard speech recognizers with this information. Previ-
ous work on sentence segmentation used lexical and prosodic fea-
tures from news broadcasts and spontaneous telephone conversa-
tions [4]. Work on multiparty meetings has been more recent.

Following the similar approaches taken for sentence segmenta-
tion (such as [4]) we treated the segmentation task as a word bound-
ary classification problem. To this end we built hybrid models com-
bining hidden event language models (HELMs) with a discrimina-
tive classifier, namely Boosting exploiting additional prosodic fea-
tures such as pitch, energy, pause, and duration characteristics. The
main idea in this hybrid approach is converting the posterior prob-
abilities obtained from Boosting into state observation likelihoods.
Then the most likely word boundary tag sequence is found using
Viterbi decoding.

In contrast to two-party dialogs, multiparty meetings present
new challenges to this problem. Consider the following sentence:
“and um if you can get that binding point also maybe with an exam-
ples that would be helpful for John and me”. The challenge here is to
use gaze and dialog context to identify the person marked by “you”
and to resolve any linguistic or gestural references to individuals or
present objects such as “John”.

The addressee identification task is typically approached as an
utterance-level classification where some subset of the participants
in the meeting are identified as addressees. [9] used a combination of
lexical features of the utterance and gaze features from each par-
ticipant to detect addressees in 4-person meetings using Bayesian
networks. For their system, using cues from multiple modalities
proved most effective. But to overcome situations where video is
unavailable or gaze tracking is difficult, the CALO system lever-
ages deeper structural, durational, and lexical features taken from
the speech transcript only [10]. In addition, a conditional random field (CRF) is used to model discourse context, explicitly modeling forward and backward dependencies in the dialog.

The need for deeper linguistic understanding of the dialog is particularly evident with the problem of pronoun referentiality. Especially in human-human conversation, words like “you” and “it” are frequently used in nonreferential and indefinite senses (e.g., “it’s raining” or “you really need an umbrella in Seattle”). As a preprocessor to a downstream reference resolution system, [11] used a rule induction classifier to determine whether “it” was referential in meetings from the ICSI corpus. For the CALO system, a CRF is used to perform the related classification of second-person pronouns into referential and generic senses [10].

7. TOPIC IDENTIFICATION AND SEGMENTATION

Identifying topic structure provides a user with the basic information of what people talked about when, and can also feed into further processing (enabling topic-based summarization, browsing and retrieval). Topic modeling can be seen as two subtasks: segmentation, dividing the speech data into topically coherent units (answering the “when” question), and identification, extracting some representation of the topics discussed therein (the “what”). While both tasks have been widely studied for broadcast news, meetings pose a different problem, being typically more coherent overall with less-sharp topic boundaries.

Segmentation is typically approached by tracking changes in lexical distribution (following text-based methods, e.g., [12]). Many variants of this approach, either using lexical distribution function directly, or incorporating it into a discriminative classifier, have been applied successfully to meeting transcripts [13, 14, among others].

As there is more to meeting dialog than the words it contains, performance can often be improved by adding features of the interaction itself, from simple prosodic features to higher-level changes in discourse structure and the behavior of the participants [13, 14, among others] or even exploiting the participants’ note-taking behavior [15]. The identification problem can then be approached as a separate step after segmentation using supervised discriminative techniques to classify topic segments according to a known list of existing topics [16].

However, there may be reason to treat the two as joint problems: segmentation can depend on the topics of interest, and these topics are not necessarily known beforehand. [17] investigated the use of Latent Semantic Analysis, learning vector-space models of topics and using them as the basis for segmentation, but accuracy was low.

Instead, we therefore use a generative topic model with a variant of Latent Dirichlet Allocation to learn models of the topics automatically, without supervision, while simultaneously producing a segmentation of the meeting [18]. Segmentation performance is competitive with that of a lexical cohesion approach ($F_k$ between 0.27 and 0.33 on the ICSI Meeting Corpus) and robust to ASR errors, while the topic models learned can be used to extract lists of descriptive keywords that human judges rate well for coherence.

8. ACTION ITEM AND DECISION EXTRACTION

Among the most commonly requested outputs from meetings are lists of the decisions made, and the action items assigned (public commitments to perform particular tasks). This requires two steps: detection of the task or decision discussion, and extraction of some concise descriptive representation (for action items, typically the task itself together with the due date and responsible party; for decisions, perhaps the issue involved and the resolved course of action).

One approach to detection might be as binary classification: classifying utterances as decision- or action item-related or not. In email text, this has shown good performance: F-scores around 0.8 when detecting relevant messages, and 0.6-0.7 for individual sentences [19, 20]. However, applying this to meeting dialog (see [21] for decisions, [22] for action items) gives poor results, with F-scores around 0.3 to 0.35. Given the nature of meeting dialog, this may not be surprising: tasks and decisions tend not to be contained within individual sentences, but are defined incrementally, with commitment being established through the interaction and the related discourse structure.

The CALO system therefore takes a structural approach to detection: utterances are classified according to their role in the commitment process (e.g. task definition, agreement, acceptance of responsibility), and then action item or decision discussions detected from patterns of these roles. This significantly improves detection performance, achieving F-scores around 0.45 for action items [23] and 0.6 for decisions [24].

The extraction problem can be approached by parsing: [19]’s email system builds logical forms from the relevant sentences and then generates descriptions via a realizer. With spoken language and ASR output, the parsing problem is more difficult; a parsing-based approach works well in some cases, but in general gives no improvement over a baseline of returning the 1-best utterance transcripts for the relevant utterances [23]. Better performance is now being shown using a lexical approach, extracting important words using classifiers or sequence models [25].

9. MEETING SUMMARIZATION

The goal of summarization is to create a shortened version of a text or speech while keeping the important points. While textual document summarization is a well-studied topic, speech summarization (and in particular meeting summarization) is an emerging research area, and apparently very different from text or broadcast news summarization. While hot spot detection, action item extraction, dialog act tagging, and topic segmentation and detection methods can be used to improve summarization, there are also preliminary studies using lexical, acoustic, prosodic, and contextual information.

In text or broadcast news summarization, the dominant approach is extractive summarization where “important” sentences are concatenated to produce a summary. For meeting summarization it is not clear what constitutes an important utterance. In an earlier study the sentences having the most number of frequent content words are considered to be important [26]. Using the advances in written and spoken document extractive summarization [27], some recent studies focused on feature-based classification approaches [28], while others mainly used maximum marginal relevance (MMR) [29] for meeting summarization [28, 30]. MMR iteratively selects utterances most relevant to a given query, which is expected to encode the user’s information need, while trying to avoid utterances redundant to the already-selected ones. Due to the lack of a query, the common approach for meetings has been using the centroid vector of the meeting as the query [28].

Our summarization work mainly focused on investigating the boundaries of extractive meeting summarization in terms of different evaluation measures [31]. We proposed a method to compute “oracle” summaries that extract a set of sentences maximizing the ROUGE performance measure [31]. In our experiments with the ICSI meeting corpus, we observed much lower oracle performance for meetings than for text, indicating that the extractive approach is unlikely to work as well as for textual news. Moreover, in meetings the information is usually distributed across multiple sentences,
making simple extraction ineffective. We also presented a very simple baseline (that extracts the longer sentences) that beats most of the proposed approaches on ROUGE scoring, suggesting that this metric might not be very suitable for meetings, and evaluation methods that are specifically designed for meeting summarization can be helpful. Finally, current extractive methods force the user to recontextualize the information by looking at the meeting itself, a rather time-consuming task. Keywords or other representations including action item and decision lists might be more informative in less time. We proposed using a set of keywords and key phrases extracted from meetings, as a query for the MMR algorithm [32]. While this resulted in better summarization performance, it also allows the users to interactively modify the set of keywords, as well as the length of the summary, according to their information needs.

10. CONCLUSIONS

We have presented a system for automatic processing of tasks involving multi-party meetings. Progress in these tasks, from low-level transcription to higher-level shallow understanding functions, such as action item extraction and summarization, has a potentially enormous impact on human productivity in many professional settings. Further integration of these tasks and multiple potential modalities, such as speech and video, is part of the future work.
